

## CHAPTER 4: CHEMICAL COMPOSITION OF THE CELL

### Fats and Health

#### 1. Triglycerides

- (a) They are a major form of fat (~95%) in foods and in the human body.
  - (a) They may be **saturated**, **polyunsaturated** or **monounsaturated** (*see no. 2*).
  - (b) The triglyceride level in the blood is raised by the intake of excessive amounts of fat and alcohol.
  - (c) The triglyceride level can be reduced by going on a low-fat diet, weight loss, exercise, smoking cessation and taking alcohol in moderation.
2. The **three** types of fats (as *discussed in the main Malaysian Biology textbooks*) are...
- (a) saturated fats,
  - (b) monounsaturated fats,
  - (c) polyunsaturated fats.

#### 3. High-density lipoprotein (HDL)

- (a) It is a form of 'good' blood cholesterol.
- (b) It removes excess cholesterol from the artery walls and carries it to the liver to be eliminated.

#### 4. Low-density lipoprotein (LDL)

- (a) It is a form of "bad" blood cholesterol.
- (b) It transports cholesterol to the arteries, starting the formation of plaques and arteriosclerosis (*see unit 6.3.2, page 159 and Figure 6.21, page 161, Nexus SPM Biology*).

#### 5. Fats and health

- (a) Some types of fats are bad for human health, but some types of fats are essential for human health.
- (b) The following table is a summary on the health implications of different types of fats.

*Types of fats and health implications*

Types of fats	Characteristics	Source	Health implication
<b>Saturated fats</b>	<ul style="list-style-type: none"> <li>All the bonds between the carbon atoms are single bonds.</li> <li>They are solid at room temperature.</li> <li>Examples: butter, lard, body fat</li> </ul>	<ul style="list-style-type: none"> <li>All animal products (e.g. fatty fresh and processed meats, skin and fat of poultry, egg yolk, dairy products) and some vegetable oils (e.g. coconut oil)</li> </ul>	<ul style="list-style-type: none"> <li>Raises the blood cholesterol (LDL and HDL) levels and the net overall effect is more harmful than good</li> <li>Increase the risk of coronary artery disease (heart attack or stroke may occur)</li> </ul>
<b>Monounsaturated fats</b>	<ul style="list-style-type: none"> <li>There is one double bond, e.g. omega 9.</li> <li>They exist as oil at room temperature.</li> </ul>	<ul style="list-style-type: none"> <li>Most nuts, olive oil, peanut oil, canola (rapeseed) oil, avocado, and palm oil</li> </ul>	<ul style="list-style-type: none"> <li>Lowers the blood cholesterol (LDL) and triglyceride levels</li> <li>Raises the level of 'good' cholesterol (HDL)</li> <li>Improves vascular health</li> </ul>
<b>Polyunsaturated fats</b>	<ul style="list-style-type: none"> <li>More than one double bond exist, e.g. omega 3 and omega 6.</li> <li>They exist as oil at room temperature.</li> </ul>	<ul style="list-style-type: none"> <li>Most nuts, corn oil, soybean oil, sunflower oil and fatty fish (e.g. salmon is rich in omega 3), and palm oil</li> </ul>	<ul style="list-style-type: none"> <li>Lowers the blood 'bad' cholesterol (LDL) level and triglyceride level</li> <li>Reduces the risk of stroke and heart attack (<i>see unit 6.3.2, page 159 Nexus SPM Biology</i>)</li> </ul>

**6. Trans-fatty acids**

- They are a class of **man-made** fats (*see unit 10.6, point no. 2, page 355, Nexus SPM Biology*).
- They are formed from naturally occurring **cis-unsaturated fatty** acids by the process of **hydrogenation** (liquid oils are turned into solid fats by adding hydrogen).
- They are used to enhance flavour, stability and prolong the shelf life of foods.
- They are bad for health as they increase the LDL level, decrease the HDL level, and increase the risk of coronary heart disease.
- They are found in margarine (made from hydrogenation of vegetable oil) and shortenings (for making crackers, cookies and snack foods).
